1 Introduction

Bold font denotes C and C++ keywords.

Courier font denotes HTTP header content, HTML, XML, XML schema content and WSDL content.

[Optional] denotes an optional construct.

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC-2119.

3 Di erences Between gSOAP Versions 2.4 (and Earlier) and 2.5

To comply with WS-I Basic Pro le 1.0a, gSOAP 2.5 and higher adopts SOAP RPC literal by default. There is no need for concern, because the WSDL parser wsdl2h automatically takes care of the di erences when you provide a WSDL document, because SOAP RPC encoding, literal, and document style are supported. A new soapcpp2 compiler option was added -e for backward compatibility with gSOAP 2.4 and e) to adopt SOAP o

to develop a service that uses SOAP encoding. You can also use the gSOAP compiler directives to specify SOAP encoding for individual operarations, when desired.

4 Di erences Between gSOAP Versions 2.1 (and Earlier) and 2.2

gSOAP runtime environment API) and the functions in the sources generated by the gSOAP compiler (the gSOAP RPC+marshalling API). Therefore, clients and services developed with gSOAP 1.X need to be modiled to accommodate a change in the calling convention used in 2.X: In 2.X, all

Section 8.2.4 presents a multi-threaded stand-alone Web Service that handles multiple SOAP requests by spawning a thread for each request.

Interoperability

4S4C

6 Interoperability
gSOAP interoperability has been veri ed with the following SOAP implementations and toolkits:
Apache 2.2
Apache Axis
ASP.NET
Cape Connect
Delphi
easySOAP++
eSOAP
Frontier
GLUE
Iona XMLBus
kSOAP
MS SOAP
Phalanx
SIM
SOAP::Lite
SOAP4R
Spray
SQLData
Wasp Adv.
Wasp C++
White Mesa
xSOAP
ZSI

7 Getting Started

clients and SOAP Web services can be developed in C and C++ with the gSOAP compiler without

The input and output parameters of a SOAP service method may be simple data types or compound data types, either generated by the WSDL parser or speci ed by hand. The gSOAP stub and skeleton compiler automatically generates **serializers** and **deserializers** for the data types to enable the generated stub routines to encode and decode the contents of the parameters of the remote methods in XML.

8.1.1 Example

The getQuote remote method of XMethods Delayed Stock Quote service (de ned in the quote.h le obtained with the 'wsdl2h' WSDL parser) provides a delayed stock quote for a given ticker name. The WSDL description of the XMethods Delayed Stock Quote service provides the following details:

Endpoint URL: http://services.xmethods.net:80/soap

SOAP action: "" (2 quotes)

Remote method namespace: urn: xmethods-del ayed-quotes

Remote method name: getQuote

Input parameter: symbol of type xsd: string
Output parameter: Result of type xsd: float

The following getQuote.h

The use of the namespace pre x ns1_ in the remote method name in the function prototype declaration is discussed in detail in 8.1.2. Basically, a namespace pre x is distinguished by a **pair of underscores** in the function name, as in ns1_getQuote where ns1 is the namespace pre x and getQuote is the remote method ace (A single underscore in an identi er ace will b translated into a dash in XML, because dashes are more frequently used in XML compared to underscores, se Section 10.3.)

The gSOAP compiler is invoked from the command line with:

soapcpp2 getQuote.h

The compiler generates the stub routine for the getQuote remote method sp in the getQuote.h header I This stub routine can b called by a client program at any time to request a stock quote from the Delayed Ca5.4 the namespace tservics

When successful, the stub returns SOAP_OK and quote contains the latest stock quote. Otherwise,

guarantee exclusive access to runtime environments by threads. Also the use of any client calls within an active service method requires a new environment.

When the example client application is invoked, the SOAP request is performed by the stub routine soap_call_ns1__getQuote, which generates the following SOAP RPC request message:

```
POST /soap HTTP/1.1
Host: services.xmethods.net
Content-Type: text/xml
Content-Length: 529
SOAPAction: ""
<?xml version="1.0" encoding="UTF-8"?>
<SOAP-ENV: Envel ope xml ns: SOAP-ENV="http://schemas.xml soap.org/soap/envel ope/"
  xml ns: SOAP-ENC="http://schemas.xml soap.org/soap/encoding/"
  xml ns: xsi = "http://www.w3.org/2001/XMLSchema-instance"
  xml ns: xsd="http://www.w3.org/2001/XMLSchema"
  xml ns: ns1="urn: xmethods-del ayed-quotes"
  SOAP-ENV: encodi ngStyl e="http://schemas.xml soap.org/soap/encodi ng/">
<SOAP-ENV: Body>
<ns1: getQuote>
<symbol > I BM</symbol >
</ns1: getQuote>
</SOAP-ENV: Body>
</SOAP-ENV: Envel ope>
```

The XMethods Delayed Stock Quote service responds with the SOAP response message:

```
HTTP/1.1 200 OK
Date: Sat, 25 Aug 2001 19:28:59 GMT
Content-Type: text/xml
Server: Electric/1.0
Connection: Keep-Alive
Content-Length: 491
<?xml version="1.0" encoding="UTF-8"?>
<soap: Envel ope xml ns: soap="http://schemas.xml soap.org/soap/envel ope/"</pre>
  xml ns: xsi = "http://www.w3.org/2001/XMLSchema-instance"
  xml ns: xsd="http://www.w3.org/2001/XMLSchema"
  xml ns: soapenc="http://schemas.xml soap.org/soap/encoding/"
  soap: encodi ngStyl e="http://schemas.xml soap.org/soap/encodi ng/">
<soap: Body>
<n: getQuoteResponse xml ns: n="urn: xmethods-del ayed-quotes">
<Result xsi: type="xsd: float">41.81</Result>
</n: getQuoteResponse>
</soap: Body>
</soap: Envel ope>
```

The server's SOAP RPC response is parsed by the stub. The stub routine further demarshalls the data of Result element of the SOAP response and stores it in the quote parameter of soap_call_ns1__getQuote.

```
struct soap soap;
  oat quotes[3]; char *myportfolio[] = f"IBM", "MSDN"g;
soap_init(&soap); // need to initialize only once
for (int i = 0; i < 3; i++)
  if (soap_call_ns1__getQuote(&soap, "http://services.xmethods.net:80/soap", "", myportfolio[i], &quotes[i]) != SOAP_OK)
    break;
if (soap.error) // an error occurred
    soap_print_fault(&soap, stderr);
soap_end(&soap); // clean up all deserialized data
...</pre>
```

This client composes an array of stock quotes by calling the ns1__getQuote stub routine for each

The rst four namespace entries in the table consist of the standard namespaces used by the SOAP 1.1 protocol. In fact, the namespace mapping table is explicitly declared to enable a programmer to specify the SOAP encoding style and to allow the inclusion of namespace-pre x with namespace-name bindings to comply to the namespace requirements of a speci c SOAP service. For example, the namespace pre x ns1, which is bound to urn: xmethods-del ayed-quotes by the namespace mapping table shown above, is used by the generated stub routine to encode the getQuote request. This is performed automatically by the gSOAP compiler by using the ns1 pre x of the ns1_getQuote method name speci ed in the getQuote.h header le. In general, if a function name of a remote method, struct name, class name, enum name, or eld name of a struct or class has a pair of underscores, the name has a namespace pre x that must be de ned in the namespace mapping table.

The namespace mapping table will be output as part of the SOAP Envelope by the stub routine. For example:

```
<<SOAP-ENV: Envel ope xml ns: SOAP-ENV="http://schemas.xml soap.org/soap/envel ope/"
xml ns: SOAP-ENC="http://schemas.xml soap.org/soap/encodi ng/"
xml ns: xsi="http://www.w3.org/2001/XMLSchema-instance"
xml ns: xsd="http://www.w3.org/2001/XMLSchema"
xml ns: ns1="urn: xmethods-del ayed-quotes"
SOAP-ENV: encodi ngStyl e="http://schemas.xml soap.org/soap/encodi ng/">
```

The namespace bindings will be used by a SOAP service to validate the SOAP request.

```
g;
class s__Address // a street address
f
    char *street;
    int number;
    char *city;
a;
```

The namespace pre x is separated from the name of a data type by a pair of underscores (__).

An instance o -11.955 Td[(cha)2871.696 0 Td[(e)]TJ ET -366.837 -18.246 2.989 0.398 re f -361.59 -18.246 2.989 0

nyspac's:paddress'> ="string">Technology Drive</street> e="int">5</number> string">Softcity</city>

ineg table of the client program must have entries forcha

```
//gsoap ns1 service encoding: encoded
//gsoap ns1 service method-action: getQuote ""
int ns1_getQuote(char *symbol, oat &Result);
```

The rst three directives provide the service name which is used to name the proxy class, the service location (endpoint), and the schema. The forth and fth directives specify that SOAP RPC encoding is used, which is required by this service. The last directive de nes the optional SOAPAction, which is a string associated with SOAP 1.1 operations. This directive must be provided for each remote method when the SOAPAction is required. Compilation of this header le with the gSOAP compiler soapcpp2 creates a new le soapQuoteProxy.h with the following contents:

#include "soapH.h"
class Quote
f public:
 struct soap *soap;
 const charsoapoin

8.1.5 XSD Type Encoding Considerations

Many SOAP services require the explicit use of XML schema types in the SOAP payload. The

For example, when an xsd: string:	the client	application	calls the pr	oxy, the prox	xy produces a	SOAP reques	st with

// Contents of le "getNames.h": int ns3__getNames(char *SSN, struct

```
struct Namespace namespaces[] =

f

f''SOAP-ENV", "http://schemas.xmlsoap.org/soap/envelope/"g,
f''SOAP-ENC","http://schemas.xmlsoap.org/soap/encoding/"g,
f''xsi", "http://www.w3.org/2001/XMLSchema-instance"g,
f''xsd", "http://www.w3.org/2001/XMLSchema"g,
f''ns1", "urn:galdemo: ighttracker"
```

```
SOAP-ENV: encodi ngStyl e="http://schemas.xml soap.org/soap/encodi ng/">
<return xml ns: ns2="http://gal demo.flighttracker.com" xsi:type="ns2:FlightInfo">
<equi pment xsi:type="xsd:stci ng">A320</equi pment>
<airline xsi:type="xsd:stci ng">UAL</airline>
<currentLocation xsi:type="xsd:stci ng">188 mi W of Lincoln, NE</currentLocation>
<altitude xsi:type="xsd:stci ng">37000</altitude>
<speed xsi:type="xsd:stci ng">497</speed>
<flightNumber xsi:type="xsd:stci ng">184</flightNumber>
</return>
</ns1:getFlightInfoResponse>
</SOAP-ENV:Body>
</SOAP-ENV:Envel ope>
```

The 'br'sxy retitums the se2ng" .096. 976 -11. 777 2. 989 0. 398 re f 1 0 0185. 093. 986 -11. 9 0 cm BT / The proxy returns the service response in variable r of type stcuct ns1_getFlightInfoResponse and this information can be displayed by the client application with the following code fragment:

```
cout << r.return_.equipment << " ight " << r.return_.airline << r.return_. ightNumb7(e)-3r << " traveling "
```

Or, alternatively with a response **struct**:

```
// Contents of "getQuote.h":
typedef char *xsd__string;
typedef oat xsd__ oat;
struct ns1__getQuoteResponse fxsd__ oat _return;g;
int ns1__getQuote(xsd__string symbol, struct ns1__getQuoteResponse &r);
```

8.1.15 How to Specify a Method with No Output Parameters

To specify a remote method that has no output parameters, just provide a function prototype with a response struct that is empty. For example:

enum ns_event f o , on, stand_by g; int ns_signal(enum ns_event in, struct ns_signalResponse f g *out);

as the xsd: double

f" SOAP-ENV", "http://schemas.xmlsoap.org/soap/envelope/" g, f" SOAP-ENC", "http://schemas.xmlsoap.org/soap/encoding/" g, f" xsi", "http://www.w3.org/2001/XMLSchema-instance" g, f" xsi", type xsi", type

8.2.2 MSVC++ Builds

Win32 builds need winsock.dll (MS Visual C++ "wsock32.lib") To do this in Visual C++

```
fprintf(stderr, "Socket connection successful: master socket = %d\n", m);
for (int i = 1; ; i++)
f
    s = soap_accept(&soap);
    if (s < 0)
    f
        soap_print_fault(&soap, stderr);
        break;
g
fprintf(stderr, "%d: accepted connection from IP=%d. %d. %d. %d socket=%d", i,
        (soap.ip > >24)&0xFF, (soap.ip > >16)&0xFF, (soap.ip > >8)&0xFF, soap.ip&0xFF, s);
    if (soap_serve(&soap) != SOAP_
```

8.2.4 How to Create a Multi-Threaded Stand-Alone Service

break;

 $g \\ fprintf(stderr, "Thread %d accepts socket %d connection from IP %d.%d.%d.%d\n", <math>$i_{>}$$ $$\% = $i_{>}$$ $$i_{>}$$ $$i_{>}$$ $$i_{>}$$

```
m = soap_bind(&soap, NULL, port, BACKLOG);
                if (m < 0)
                         exit(1);
                 fprintf(stderr, "Socket connection successful %d\n", m);
                 for (i = 0; i < MAX_THR; i++)
                         soap_thr[i] = NULL;
                for (;;)
                         for (i = 0; i < MAX_THR; i++)
                                 s = soap_accept(&soap);
                                if (s < 0)
                                        break;
                                 fprintf(stderr, "Thread %d accepts socket %d connection from IP %d.%d.%d.%d\n",
i, s, (soap.ip >> 24)\&0xFF, (soap.ip >> 16)\&0xFF, (soap.ip >> 8)\&0xFF, soap.ip\&0xFF);
                                 if (!soap_thr[i]) // rst time around
                                         soap_thr[i] = soap_copy(&soap);
                                         if (!soap_thr[i])
                                         exit(1); // could not allocate
                                 else // recycle soap environment
                                         pthread_join(tid[i], NULL);
                                         fprintf(stderr, "Thread %d completed\n", i);
                                         soap\_destroy(soap\_thr[i])59.775 2.989 0.398 ref 1 0 0 1 -1.176 -59.77-02 0 2.989 1.955 T7[(g)]TTJ/F1C++0 2.989 1.989 1.989 T7[(g)]TTJ/F1C++0 2.989 1.989 1.989 T7[(g)]TTJ/F1C++0 2.989 1.989 T7[(g)]TTJ/F1C++0 2.989 1.989 T7[(g)]TTJ/F1C++0 2.989 1.989 T7[(g)]TTJ/F1C++0 2.989 T7[(g)]TTJ/F1C-+0 2
```

8.2.5 How to Pass Application Data to Service Methods

The void *soap.user

//gsoap ns service location: http://www.cs.fsu.edu/~engelen/calc.cgi //gsoap ns schema namespace: urn:calccalc.cgi

In addition to the generation of the ns. wsdl le, a le with a namespace mapping table is generated by the qSOAP compiler. An example mapping table is shown below:

```
struct Namespace namespaces[] = 
f

f"SOAP-ENV", "http://schemas.xmlsoap.org/soap/envelope/"g,
f"SOAP-ENC", "http://schemas.xmlsoap.org/soap/encoding/"g,
f"xsi", "http://www.w3.org/2001/XMLSchema-instance", http://www.w3.org/*/XMLSchema-instance"g,
f"xsd", "http://www.w3.org/2001/XMLSchema", http://www.w3.org/*/XMLSchema"g,
f"ns", "http://tempuri.org"g,
fNULL, NULLg

g;
```

This le can be incorporated in the client/service application, see Section 10.4 for details on namespace mapping tables.

To deploy a Web service, copy the compiled CGI service application to the designated CGI directory of your Web server. Make sure the proper le permissions are set (chmod 755 cal c. cgi for Unix/Linux). You can then publish the WSDL le on the Web by placing it in the appropriate Web server directory.

The gSOAP compiler also generates XML schema les for all C/C++ complex types (e.g. **structs** and **class**es) when declared with a namespace pre x. These les are named

```
<schema
    xml ns="http://www.w3.org/2000/10/XMLSchema"
    targetNamespace="http://tempuri.org"
    xml ns: SOAP-ENV="http://schemas.xml soap.org/soap/envel ope/"
    xml ns: SOAP-ENC="http://schemas.xml soap.org/soap/encoding/">
    <compl exType name="addResponse">
      <all>

8.2.11 How to Use Client Functionalities Within a Service

A gSOAP service may make client calls to other services from within its remove methods. This is best illustrated with an example. The following example is a more sophisticated example that combines the functionality of two Web services into one new SOAP Web service. The service provides a currency-converted stock quote. To serve a request, the service in turn requests the

```
return SOAP_OK;

g
soap->socket = socket;
return SOAP_FAULT; // pass soap fault messages on to the client of this app

g
/* Since this app is a combined client-server, it is put together with
one header le that describes all remote methods. However, as a consequence we
have to implement the methods that are not ours. Since these implementations are
never called (this code is client-side), we can make them dummies as below.
/
int ns1__getQlb

SOAPOK;
/*etsoaps:thress=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=faires=
```

8.3 How to Use gSOAP for Asynchronous One-Way Message Passing

SOAP RPC client-server interaction is synchronous: the client blocks until the server responds

8.4	How to Use the SOAP Serializers and Deserializers to Save and Load Ap)-
	olication Data	

The gSOAP stub and skeleton compiler generates serializers and deserializers for all user-de ned

Туре	Type Name
char*	string
wchar_t*	wstring
char	byte
bool	bool
double	double
int	int
oat	oat
long	long
LONG64	LONG64 (Win32)
long long	LONG64 (Unix/Linux)
short	short
time_t	time
unsigned char	unsignedByte
unsigned int	unsignedInt
unsigned long	unsignedLong
ULONG64	unsignedLONG64 (Win32)
unsigned long long	unsignedLONG64 (Unix/Linux)
unsigned short	unsignedShort
<u>T[N]</u>	ArrayNOfType where Type is the type name of \underline{T}
<u>T</u> *	PointerToType where $\overline{\text{Type}}$ is the type name of $\underline{\text{T}}$
struct Name	Name ———
class Name	Name
enum Name	Name

Consider for example the following C code with a declaration of p as a pointer to a **struct** ns__Peraon:

struct ns__Peraon f char *name; g *p;

To serialize p_{\star} its address is passed to the function soap serialize_PointerTons__Peraon generated for this type by the gSOAP compiler:

soap_serialize_PointerTons__

soap_end() function. The soap_

where <u>Type1</u> is the type named <u>offype2</u> is the type named above). The s namespace-pre x: type-name1 and namespace-pre x: type-name2 describe the schema types of the ss. Use NULL to omit this type information.

ializing class instances, method invocations MUST be used instead of function calls, for

e obj.soap

serialize(&soap)phyt(#33(#36)44)1451451451451451514551455165145550

Consider the following struct:

```
// Contents of le "tricky.h":
struct Tricky
f
  int *p;
  int n;
  int *q;
g;
```

The following fragment initializes the pointer elds p and q to the value of eld n:

```
struct soap soap;
struct Tricky X;
X.n = 1;
X.p = &X.n;
X.q = &X.n;
soap_init(&soap);
soap_begin(&soap);
soap_serialize_Tricky(&soap, &X);
soap_put_Tricky(&soap, &X, "Tri cky", NULL);
soap_end(&soap); // Clean up temporary data used by the serializer
```

What is special about this data structure is that n is 'xed' in the Tricky structure, and p and q both point to n. The gSOAP serializers strategically place the id-ref attributes such that n will be identified as the primary data source, while p and q are serialized with ref/href attributes.

The resulting output is:

```
<Tricky xsi:type="Tricky">
 <n xsi:type="int">1</n> <q href="#2"/> <r xsi:type="int">2</r> </Tricky>
<id id="2" xsi:type="int">1</id>
```

struct soap soap;

. . .

soap_init(&soap); // initialize at least once
[soap_imode(&soap, ags);] // set input-mode ags
soap_

 $soap_end(\&soap); // remove temporary data, including the decoded data on the heap <math>soap_done(\&soap); // nalize last use of the environment$

When you declare a soap struct pointer as a data member in a class, you can overload the >> operator to parse and deserialize a class instance from a stream:

istream & operator>>

```
int main()
f
    struct soap soap;
    ns__Person mother,27.7Z,aother,27.2(johnp;)]TJ 17.84 -11.955 Td[(mothe.namen)-333=t
```

```
struct Namespace namespaces[] =
f
f"SOAP-ENV", "http://schemas.xmlsoap.org/soap/envelope/"g,
f"SOAP-ENC","http://schemas.xmlsoap.org/soap/encoding/"g,
f"xsi", "http://www.w3.org/2001/XMLSchema-instance"g,
f"xsd", "http://www.w3.org/2001/XMLSchema"g,
f
```

```
jj p->soap_in(p.soap, NULL, NULL)
jj soap_end_recv(p.soap))
; // handle I/O error
return i;
g
```

8.4.5 How to Specify Default Values for Omitted Data

The gSOAP compiler generates soap_default functions for all data types. The default values of the

```
int ns__login(char *uid = "anonymous", char *pwd = "guest", bool granted);
```

When the request message lacks uid and pwd parameters, e.g.:

```
<?xml version="1.0" encoding="UTF-8"?>
<SOAP-ENV: Envel ope
  xml ns: SOAP-ENV="http://schemas.xml soap. org/soap/envel ope/"
  xml ns: SOAP-ENC="http://schemas.xml soap. org/soap/encodi ng/"
  xml ns: xsi="http://schemas.xml soap. org/soap/encodi ng/"
  xml ns: xsd="http://www.w3.org/2001/XMLSchema-instance"
  xml ns: xsd="http://www.w3.org/2001/XMLSchema"
  xml ns: ns="http://tempuri.org">
        <SOAP-ENV: Body encodi ngStyl e="http://schemas.xml soap.org/soap/encodi ng/">
        <ns: login>
        </ns: login>
        </sOAP-ENV: Body>
</SOAP-ENV: Envel ope>
```

then the service uses the default values. In addition, the default values will show up in the SOAP/XML request and response message examples generated by the gSOAP compiler.

9 Using the gSOAP Stub and Skeleton Compiler

The gSOAP stub and skeleton compiler is invoked from the command line and optionally takes the name of a header—le as an argument or, when the—le name is absent, parses the standard input:

```
soapcpp2 [aheader le.h]
```

where aheader le.h is a standard C++ header le. The C++ act aa-279(aprepr)-36(Tcssao+)-4.1and prdeucss]TJ - STe s014le.s-533(gSnerated)-3343by the C++ arge

<xsd: doubl e xsi : type="xsd: doubl e">. . . </xsd: doubl e>

xsd: duration

Another possibility is to use strings to represent unbounded integers and do the translation in code.

xsd: I ong

typedef char *xsd__normalizedString;

Type xsd__normalizedString declares a string type which is encoded as

<xsd: normalizedString xsi: type="xsd: normalizedString">...</xsd: normalizedString>

It is solely the responsibility of the application to make sure the strings do not contain carriage return (#xD), line feed (#xA) and tab (#x9) characters.

xsd: positiveInteger Corresponds to a positive unbounded integer (0). Since C++ does not

xsd: token Represents tokenized strings. Tokens are strings that do not contain the line feed (#xA) nor tab (#x9) characters, that have no leading or trailing spaces (#x20) and that have no internal sequences of two or more spaces. It is recommended to use strings to store xsd: token XML schema types. The type declaration is:

typedef char *xsd__token;

Type xsd_token declares a string type which is encoded as

<xsd: token xsi : type="xsd: token">...</xsd: token>

It is solely the responsibility of the application to make sure the strings do not contain the line feed (#xA) nor tab (#x9) characters, that have no leading or trailing spaces (#x20) and

<xsd: unsi gnedShort xsi : type="xsd: unsi gnedShort">. . . </xsd: unsi gnedShort>

Other XML schema types such as gYearMonth, gYear, gMonthDay, gDay, xsd: gMonth, QName, NOTATION, etc., can be encoded similarly using a **typedef** declaration.

enumeration-type identi er's name, with the usual namespace pre x conventions for identi ers. This can be used to explicitly specify the encoding style. For example:

enum ns1__weekday f

11.3.3 Initialized Enumeration Constants

The gSOAP compiler supports the initialization of enumeration constants, as in:

enum ns1__relation f

<xsd: bool ean xsi : type="xsd: bool ean">fal se</xsd: bool ean>

accessors. This encoding is identical to the **class** instance encoding without inheritance and method declarations, see Section 11.5 for further details. However, the encoding and decoding of **structs** is more e cient compared to **class** instances due to the lack of inheritance and the requirement by the marshalling routines to check inheritance properties at run time.

Certain type of elds of a **struct** can be (de)serialized as XML attributes. See 11.5.7 for more details.

11.5 Class Instance Encoding and Decoding

A class instance is encoded as a SOAP compound data type such that the class name forms the data type's element name and schema type and the data member—elds are the data type's accessors. Only the data member—elds are encoded in the SOAP payload. Class methods are not encoded.

The general form of a class declaratior

Only single inheritance is supported by the gSOAP compiler. Multiple inheritance is not support because of the limitations of the SOAP protocol.	rted,

```
int sides;
enum ns__Color fRed, Green, Blueg color;
ns__Shape();
ns__Shape(int sides, enum ns _Green color);
~ns__Shape();
g;
```

The implementation of the methods of class ns__Shape must not be part of the header—le and need to be de ned elsewhere.

An instance of class ns. Shape with name Triangle, 3 sides, and color Green is encoded as:

```
<ns: Shape xsi: type="ns: Shape">
<name xsi: type="string">Tri angl e</name>
```

```
class update
f public:
    time_t __item;
    int set(struct soap *soap);
g;
```

The setter method assigns the current time:

```
int update::set(struct soap *soap)
f
    this->__item = time(NULL);
    return SOAP_OK;
q
```

Therefore, serialization results in the inclusion of a time stamp in XML.

Caution: a get

The method is not invoked when the element is an element or has an

```
cout << "print(): Derived class instance " << name << " " << num << endl; g
```

Below is an example CLIENT application that creates a Derived class instance that is passed as the input parameter of the remote method:

```
// CLIENT
#include "soapH.h"
int main()
f
    struct soap soap;
    soap_init(&soap);
    Derived obj1;
    Base *obj2;
    struct methodResponse r;
    obj1.name = "X";
    obj1.num = 3;
    soap_call_method(&soap, url, action, &obj1, r);
    r.obj2->print();
g
...
```

The following example SERVER1 application copies a class instance (Base or Derived class) from the input to the output parameter:

```
// SERVER1
#include "soapH.h"
int main()
f
    soap_serve(soap_new());
g
int method(struct soap *soap, Base *obj1, struct methodResponse &result)
f
    obj1->print();
    result.obj2 = obj1;
    return SOAP_OK;
g
...
```

The following messages are produced by the CLIENT and SERVER1 applications:

```
CLIENT: created a Derived class instance
SERVER1: created a Derived class instance
SERVER1: print(): Derived class instance X 3
CLIENT: created a Derived class instance
CLIENT: print(): Derived class instance X 3
```

Which indicates that the derived class kept its identity when it passed through SERVER1. Note that instances are created both by the CLIENT and SERVER1 by the demarshalling process.

```
// Contents of le "base.h":
class Base
f
   public:
    char *name;
   Base();
   virtual void print();
g;
int method(Base *in, Base *out);
```

11.5.7 XML Attributes

```
struct xsd__string
f
    char *__item;
    @ xsd__boolean ag;
a;
```

11.6 Pointer Encoding and Decoding

The serialization of a pointer to a data type amounts to the serialization of the data type in SOAP

Since both a and b elds of P point to the sace integer, the encoding of P is multi-reference:

Now, the decoding of the content in the R data structure that does not use pointers to integers results in a copy of each multi-reference integer. Note that the two **structs** resemble the sace XML

This method has a polymorphic input parameter data and a polymorphic output parameter return. The __type parameters can be one of SOAP_TYPE_xsd__string, SOAP_TYPE_xsd__int, SOAP_TYPE_xsd__ oat, SOAP_TYPE_ns__status, or SOAP_TYPE_ns__widget. The WSDL produced by the gSOAP compiler declares the polymorphic parameters of type xsd: anyType which is "too loose" and doesn't allow the gSOAP importer to handle the WSDL accurately. Future gSOAP releases might replace xsd: anyType with a choice

header le.

11.8 Fixed-Size Arrays

Fixed size arrays are encoded as per SOAP 1.1 one-dimensional array types. Multi-dimensional xed size arrays are encoded by gSOAP as nested one-dimensional arrays in SOAP. Encoding of xed size arrays supports partially transmitted and sparse array SOAP formats.

delete. Such dynamic allocations are exible, but pose a problem for the serialization of data: how does the array serializer know the length of the array to be serialized given only a pointer to the sequence of elements? The application stores the size information somewhere. This information is crucial for the array serializer and has to be made explicitly known to the array serializer by packaging the pointer and array size information within a **struct** or **class**.

11.9.1 SOAP Array Bounds Limits

SOAP encoded arrays use the

To encode the data type as an array, the name of the struct or class SHOULD NOT have a namespace

The deserializer of a dynamic array can decode

Caution: SOAP 1.2 does not support partially to

__o set eld of a dynamic

The following example header I

```
__SOAPService

f

public:
int ID;
char *name;
char *owner;
char *description;
char *homepageURL;
char *endpoint;
char *SOAPAction;
char *methodNamespaceURI;
char
```

```
__ptr = NULL;
__size = 0;
```

```
f
    __ptr = NULL;
    __size = 0;
    __o set = 1;
g
Vector::Vector(int n)
f
    __ptr = ( oat*)malloc(n*sizeof( oat));
    __size = n;
    __o set = 1;
g
Vector::~Vector()
f
    if
```

```
// Contents of le "matrix.h":
class Matrix
f
   public:
   Vector *__ptr;
   int __size;
   int __o set;
   Matrix();
   Matrix(int n, int m);
   ~Matrix();
   Vector& operator[](int i);
g;
```

The Matrix type is essentially an array of pointers to arrays which make up the rows of a matrix. The encoding of the two-dimensional dynamic array in SOAP will be in nested form.

11.9.6 Multi-Dimensional Dynamic Arrays

The general form of the **struct** declaration for K-dimensional (K > 1) dynamic arrays is:

where <u>Type</u> MUST be a type associated with an XML schema, which means that it must be a **typedef**ed type in case of a primitive type, or a **struct/class** name with a namespace pre x for schema association, or another dynamic array. If these conditions are not met, a generic vector XML (de)serialization is used (see Section 11.9.7).

An alternative is to use a **class** with optional methods:

```
class some_name
f
  public:
    Type *__ptr;
  int __size[K];
  int __o set[K];
  method1;
  method2;
    ... // any elds that follow will be ignored
g;
```

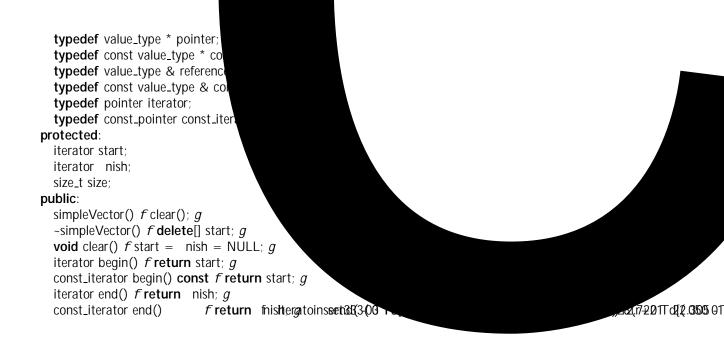

In the above, K is a constant denoting the number of dimensions of the multi-dimensional array.

To encode the data type as an array, the name of the **struct** or **class** SHOULD NOT have a namespace pre x, otherwise the data type will be encoded and decoded as a generic vector, see Section 11.9.7.

The descrializer of a dynamic array can decode partially t8-30.itiedusti-dimensional arrays

```
TF84(,r)-333(Kexampl,)-434(dhe)-333(aollo)29(w)ng se a cmtrix
```

end of the list is reached, for the dynamic array.	the bu	ered elemer	nts are copi	ed to a nev	wly allocated	space on th	ne heap

Caution: when parsing XML content the container elements may not be stored in the same order given in the XML content. When gSOAP parses XML it mses theirsert container methods to store

struct ArrayOfstring

```
class SOAP_ENC__base64
f
  unsigned char *__
```

-		
-		

WSDL in order for the gSOAP compiler to generate the (de)serialization routines. Alternatively, the optional DOM parser (dom.c and dom++.cpp) can be used to handle generic XML or arbitrary

```
soap_print_fault(&soap, stderr);
else
    printf("Time = %s\n", t);
    return 0;
g
```

To illustrate the manual doc/literal setting, the following client program sets the required properties before the call:

```
#include "soapH.h"
#include "localtime.nsmap" // include generated map le
int main()
f
    struct soap soap;
    char *t;
```

To declare a literal XML \type" to hold XML documents in wide character strings, use:

```
typedef wchar_t *XML;
```

Note: only one of the two storage formats can be used. The di erences between the use of regular strings versus wide character strings for XML documents are:

Regular strings for XML documents MUST hold UTF-8 encoded XML documents. That is, the string MUST contain the proper UTF-8 encoding to exchange the XML document in SOAP messages.

Wide character strings for XML documents SHOULD NOT hold UTF-8 encoded XML documents. Instead, the UTF-8 translation is done automatically by the gSOAP runtime marshalling routines.

Here is an example of a remote method speci cation in which the parameters of the remote method uses literal XML encoding to pass an XML document to a service and back:

```
typedef char *XML;
ns__GetDocument(XML m__XMLDoc, XML &m__XMLDoc_);
```

The ns__Document is essentially a **struct** that forms the root of the XML document. The use of the underscore in the ns__Document response part of the message avoids the name clash between the **struct**s. Assuming that the namespace mapping table contains the binding of ns to http://my.org/and the binding of m to http://my.org/mydoc.xsd, the XML message is:

```
<?xml version="1.0" encoding="UTF-8"?>
<SOAP-ENV: Envel ope
  xml ns: SOAP-ENV="http: //schemas. xml soap. org/soap/envel ope/"
  xml ns: SOAP-ENC="http: //schemas. xml soap. org/soap/encoding/"
  xml ns: xsi = "http: //schemas. xml soap. org/soap/encoding/"
  xml ns: xsi = "http: //www. w3. org/2001/XMLSchema-instance"
  xml ns: xsd="http: //www. w3. org/2001/XMLSchema"
  xml ns: ns="http: //my. org/"
  xml ns: m="http: //my. org/mydoc. xsd"
  SOAP-ENV: encodingStyl e="">
  <SOAP-ENV: Body>
  <ns: GetDocument>
  <XMLDoc xml ns="http: //my. org/mydoc. xsd">
```

The rst four elds in SOAP_

soap->fault->detail->__type = SOAP_TYPE_ns1__my\$y9d@t.DetaType; // stack type

See Section 17.2 on how to generate WSDL with the proper method-to-header-part bindings.

The SOAP-ENV: mustUnderstand

Function void soap

```
NULL, NULL);

/* send the forms as MIME attachments with this invocation */

if (soap_call_claim__insurance_claim_auto(soap, form1, form2, ...))

// an error occurred

else

// process response
```

where the claim__form

C++ programmers can use an iterator instead, as in:

```
for (soap_multipart::iterator attachment = soap.dime.begin(); attachment != soap.dime.end(); ++at-
tachment)
f
    cout << "DIME attachment:" << endl;
    cout << "Memory=" << (void*)(*attachment).ptr << endl;
    cout << "Size=" << (*attachment).size << endl;</pre>
```

elds in the struct/class, but additional elds and methods may appear after the eld declarations. An extended xsd_hexBinary declaration is similar.

The id and type elds contain text. The set the DIME-speci c options eld, you can use the soap_dime_option function:

char

f unsigned char *

Callback (function pointer) void *(*soap.fdimereadopen)(

The following example illustrates the client-side initialization of an image attachment struct to stream a le into a DIME attachment:

int main()
f
 struct

soap_init(&soap);
soap.fdimewriteopen = dime_

15.5 Streaming Chunked DIME

gSOAP automatically handles inbound chunked DIME attachments (streaming or non-streaming).

The minOccurs and maxOccurs values must be integer literals. A default value can be provided

```
typedef int time__seconds "[1-5]?[0-9] | 60";
```

This de nes the following schema type in time.xsd:

```
<simpleType name="seconds">
  <restriction base="xsd:int">
     <pattern value="[1-5]?[0-9]|60"/>
     </restriction base="xsd:int"/>
  </simpleType>
```

17.2 Customizing the WSDL and Namespace Mapping Table File Contents With gSOAP Directives

A header le can be augmented with directives for L automatically generate customized WSDL and namespace mapping tables contents. T and namespace mapping table les do not need to be modi ed by hand (Sections 8.2.8 and 10. 3spaaddi(,9(3s5)).

A shortcut to de ne the default quali cation of elements and attributes of a schema:

//gsoap namespace-pre x schema form: quali ed

or:

//gsoap namespace-pre x schema form: unquali ed

To document a method, use:

where

//gsoap namespace-pre x service method-documentation: method-name //text method-documentation: method-name //text method-documentation: method-name //text

When literal encoding is required for a particular service method response when the request message is encoded, use:

//gsoap namespace-pre x service method-response-encoding: method-name literal

or when the SOAP-ENV: encodingStyle attribute is dierent from the SOAP 1.1/1.2 encoding style, use:

//gsoap namespace-pre x service method-response-encoding: method-name encoding-style

The automatic generation and inclusion of the namespace mapping table requires compiler directives for all namespace pre xes to associate each namespace pre x with a namespace URI. Otherwise, namespace URIs have to be manually added to the table (they appear as http://tempuri.org).

17.3 Transient Data Types

soap_done(soap);
free(soap);

It is also possible th serialize the tm elds as XML attributes using the @ quali er, see Section 11.5.7.

to include the proper schema de nitions in the WSDL produced by the gSOAP compiler, you should use quali ed **struct**, **class**, and **enum** names with a leading underscore, as in:

```
struct _ns_ _myStruct
f ... g;
```

This ensures that myStruct is associated with a schema, and therefore included in the appropriate schema in the generated WSDL. The leading underscore prevents the XML serialization of xsi: type attributes for this type in the SOAP/XML payload.

17.7 Function Callbacks for Customized I/O and HTTP Handling

gSOAP provides ve callback functions for customized I/O and HTTP Tandling:

Callback (function pointer)
int (*soap.fopen)(struct soap *soap, const char *endpoint, const char *host, int port) Calledatxytoentoebcatedat endpoint. Input parameters host and port are micro-parsed SOAP_INVALID_SOCKET and soap->error endpoint. return a valid

```
g
...
soap. gnore = myignore;
soap_call_ns__method(&soap, ...); // or soap_serve(&soap)
...
struct Namespace namespaces[] =
f
f
```

```
struct soap soap;
soap_init(&soap);
...
soap.http_version = "1.0";
```

17.9 HTTP 307 Temporary Redirect Support

The client-side handling of HTTP 307 code "Temporary Redirect" and any of the redirect codes 301, 302, and 303 are not automated in gSOAP. Client application developers may want to consider adding a few lines of code to support redirects. It was decided not to automatically support redirects for the following reasons:

Redirecting a secure HTTPS address to a non-secure HTTP address via 307 creates a security vulnerability.

Cyclic redirects must be detected (e.g. allowing only a limited number of redirect levels).

cting aHTTP POST willaresult in re-serialization and re-post of the entire SOAP request. The The(dec4050e.request.-497[(mss)ag)-4979mer-497[(e-p)-28(ost)d n nty when050e.req-issu5(a)-97[(te)-4050e.req-issu5(a)-

```
soap_serve(soap);
...
int http_get(struct soap *soap)
f
    soap_response(soap, SOAP_HTML); // HTTP response header with text/html
    soap_
```

```
exit(1); g fprintf(stderr, "Socket connection successfuo3 T(1Fd\n"g)]TJ/F31 9.963 Tf183.0615 0 Td[, m1); <math display="block"> g g
```

A stand-alone gSOAP Web Service can enforce HTTP authentication upon clients, by checking the soap.userid and soap.passwd strings. These strings are set when a client request contains HTTP authentication headers. The strings SHOULD be checked in each service method (that requires authentication to execute).

Here is an example service method implementation that enforced client authentication:

bMB0411(19)vEnd(n)n293:augn;3 B4009.659nrequires

17.18 Socket Options and Flags

gSOAP's socket communications can be controlled with socket options and ags. The gSOAP run-time environment **struct** soap ags are: **int** soap.socket_ ags to control socket send() and recv() calls, **int** soap.connect_ ags to set client connection socket options, **int** soap.bind_ ags to set server-side port bind socket options, **int** soap.accept_ ags to set server-side request message accept socket options. See the manual pages ob221a.7o5 9.96e16.447 0 0 Td[(ags)]J/F32 9.9a16.447 0(pages)-319(21]TJ5F32 9.

"server.pem", /* key le: required when server must authenticate to clients (see SSL docs on how to obtain this le) */ $\,$

 $g \\ \textbf{static void } \textbf{dyn_destroy_function} \\ (\textbf{struct } \textbf{CRYPTO_dynlock_} \\$

or you can add the following line to soapdefs.h:

#de ne WITH_OPENSSL

and compile with option -DWITH_SOAPDEFS_H to include soapdefs.h

void sigpipe_handle(int x) fg

Caution: it is important that the WITH_OPENSSL macro MUST be consistently de ned to compile the sources, such as stdsoap2.cpp, soapC.cpp, soapClient.cpp, soapServer.cpp, and all application sources that include stdsoap2.h or soapH.h. If the macros are not consistently used, the application will

There should be a script called CA.sh (and a CA.pl that does the same). This hides all the

Of course the developer using your server cert on her machine will <code>nd</code> that if require_

It is also possible to convert IIS-generated certicates to PEM format, see http://www.icewarp.com/Knowledgebase/617.for example.

17.23 SSL Hardware Acceleration

You can specify a hardware engine to enable hardware support for cryptographic acceleration. This can be done once in a server or client with the following statements:

static const char *engine = "cswift"+I533*for*enginenamgine

The gzip compression is oo28Pgonal to all transpoo2 encodings such as HTTP, SSL, DIME, and can be used with other transpoo2 layers. You can even save and load compressed XML data to/from les.

gSOAP suppoo2s two compression formats: de ate and gzip. The gzip format is used by default.

and may speed up the transmission of compressed SOAP/XML messages. This is accomplished by setting the SOAP_IO

```
char *path;
long expire; /* client-side: local time to expire; server-side: seconds to expire */
unsigned int version;
short secure;
short session; /* server-side */
short env; /* server-side: 1 = got cookie from client */
short modi ed; /* server-side: 1 = client cookie was modi ed */
struct soap_cookie *next;
g;
```

Since the cookie database is linked to a soap struct, each thread has a local cookie database in a multi-threaded implementation.

17.27 Server-Side Cookie Support

Server-side cookie support is optional. To enable cookie support, compile all sources with option -DWITH_COOKIES, for example:

```
g++ -DWITH_COOKIES -o myserver ...
```

gSOAP prov /Fs the following cookie API for server-side cookie session control:

Function struct soap_cookie *soap_set_cookie(struct soap *soap, const char *name, const char *value, const

The cookie_path value is used to liter cookies intended for this service according to the path pre x rules outlined in RFC2109.

The following example server adopts cookies for session control:

```
int main()
  struct soap soap;
  int m, s;
  soap_init(&soap);
  soap.cookie_domain = "...";
  soap.cookie_path = "/"; // the path which is used to Iter/set cookies with this destination
  if (argc < 2)
    soap_getenv_cookies(&soap); // CGI app: grab cookies from 'HTTP_COOKIE' env var
    soap_serve(&soap);
  g
  else
    m = soap_bind(&soap, NULL, atoi(argv[1]), 100);
    if (m < 0)
       exit(1);
    for (int i = 1; ; i++)
       s = soap\_accept(\&soap);
       if (s < 0)
         exit(1);
       soap_serve(&soap);
       soap_end(&soap); // clean up
       soap_free_cookies(&soap); // remove all old cookies from database so no interference occurs
with the arrival of new cookies
    g
  return 0;
int ck__demo(struct soap *soap, ...)
  int n;
  const char *s;
  s = soap_cookie_value(soap, "demo", NULL, NULL); // cookie returned by client?
  if (!s)
    s = "init-value"; // no: set initial cookie value
  else
    ... // modify 's' to re ect session control
  soap_set_cookie(soap, "demo", s, NULL, NULL);
  soap_set_cookie_
seconds
  return SOAP_OK;
```

17.28 Connecting Clients Through Proxy Servers

When a client needs to connect to a Web Service through a proxy server, set the soap.proxy_host string and soap.proxy_port integer attributes of the current soap runtime environment to the proxy's host name and port, respectively. For example:

```
struct soap soap;
soap_init(&soap);
soap.proxy_host = "proxyhostname";
soap.proxy_port = 8080;
if (soap_call_
```

No logging

Limited TCP/IP and HTTP error diagnostic messages

The generated envC.cpp le holds the SOAP Header and Fault serializers and you can link this le with your client or server application.

17.32 How to Create Client/Server Libraries

The gSOAP compiler produces soapClientLib.cpp and soapServerLib.cpp codes that are speci cally intended for building static or dynamic client/server libraries. These codes export the stubs and skeletons, but keep all marshaling code (i.e. parameter serializers and deserializers) local (i.e. as

First, we create an empty header le env.h (which may contain optional SOAP Header and Fault de nitions), and compile it as follows:

We also compile stdsoap2.cpp without namespaces:

```
g++ -c -DWITH_NONAMESPACES stdsoap2.cpp
```

Note: when ou use -DWITH_NONAMESPACES 3728(ou)-299-will aned link error global namespaces table. You can de ne a dumm728(y)-333(table)-333(to)-333(a)27(v728(oid)-332(ha728(ving)-33

Similar to the Quote example above, we compile it as a library and we use option -n to rename the namespace table to avoid link con icts:

```
//gsoap ns service style: rpc
//gsoap ns service encoding: encoded
//gsoap ns service location: http://www.cs.fsu.edu/ engelen/calc.cgi
//gsoap ns schema namespace: urn:calc
int ns_add(double a, double b, double &result);
int ns_sub(double a, double b, double &result);
int ns_mul(double a, double b, double &result);
int ns_div(double a, double b, double &result);
g
```

We compile this with:

```
soapcpp2 -n calc.h
g++ -c calcServiceObject.cpp
```

The e ect of the -n option is that it creates local namespace tables, and a modi ed calcServiceObject.h server class de nitions that properly initialize the gSOAP run time with the table.

#include "calcServiceObject.h" /e.

Second, we create the Delayed Stock Quote header le speci cation, which may be obtained using the WSDL importer.

```
//gsoap ns service name: Service
//gsoap ns service style: rpc
//gsoap ns service encoding: encoded
//gsoap ns service location: http://services.xmethods.net/soap
```

To create multiple DLLs in the same project directory, you SHOULD use option -p to renam generated soapClientLib.cpp and
